

# Azimuthally differential pion femtoscopy with respect to second and third order event planes and deformation of the source shape with event engineering in Pb-Pb 2.76 TeV

Naoto Tanaka for the ALICE Collaboration  
University of Tsukuba, CiRfSE

## Motivation

In heavy ion collisions, initial geometrical fluctuation generates odd order anisotropies. But the relation between the fluctuation of initial geometry and higher order anisotropy is not trivial.

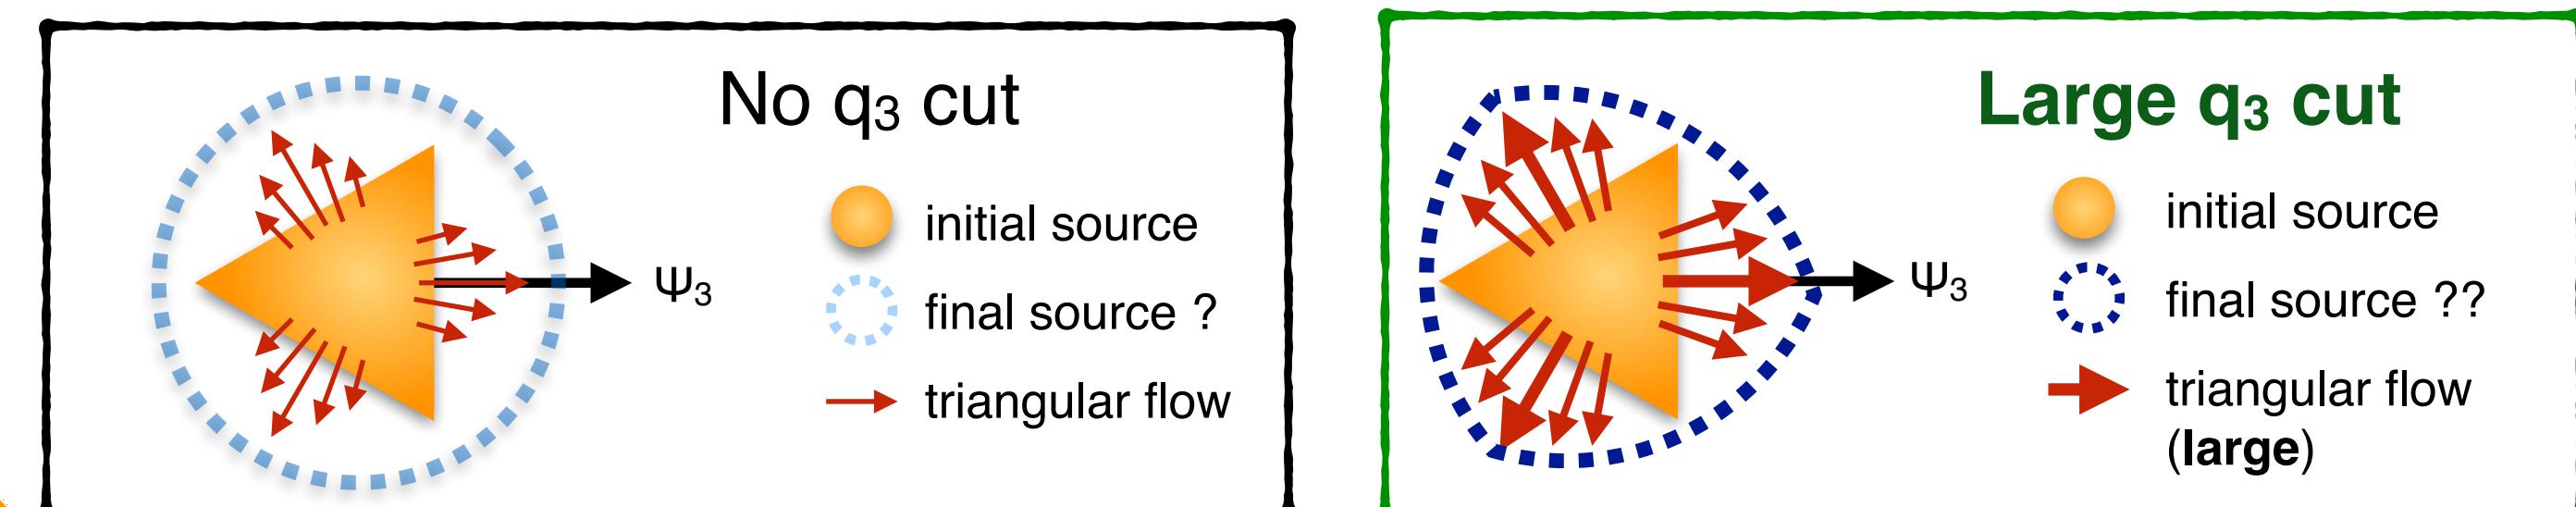

Azimuthally differential femtoscopy can help us to access the **geometrical source shape and flow velocity profile at freeze out**.

A detailed analysis of azimuthal dependence of HBT radii w.r.t. 3rd order event plane ( $\Psi_3$ ) will provide us the key to the final source triangularity.

$$\text{Event plane } \Psi_n = \frac{1}{n} \tan^{-1} \left( \frac{\sum w_i \sin(n\phi_i)}{\sum w_i \cos(n\phi_i)} \right)$$

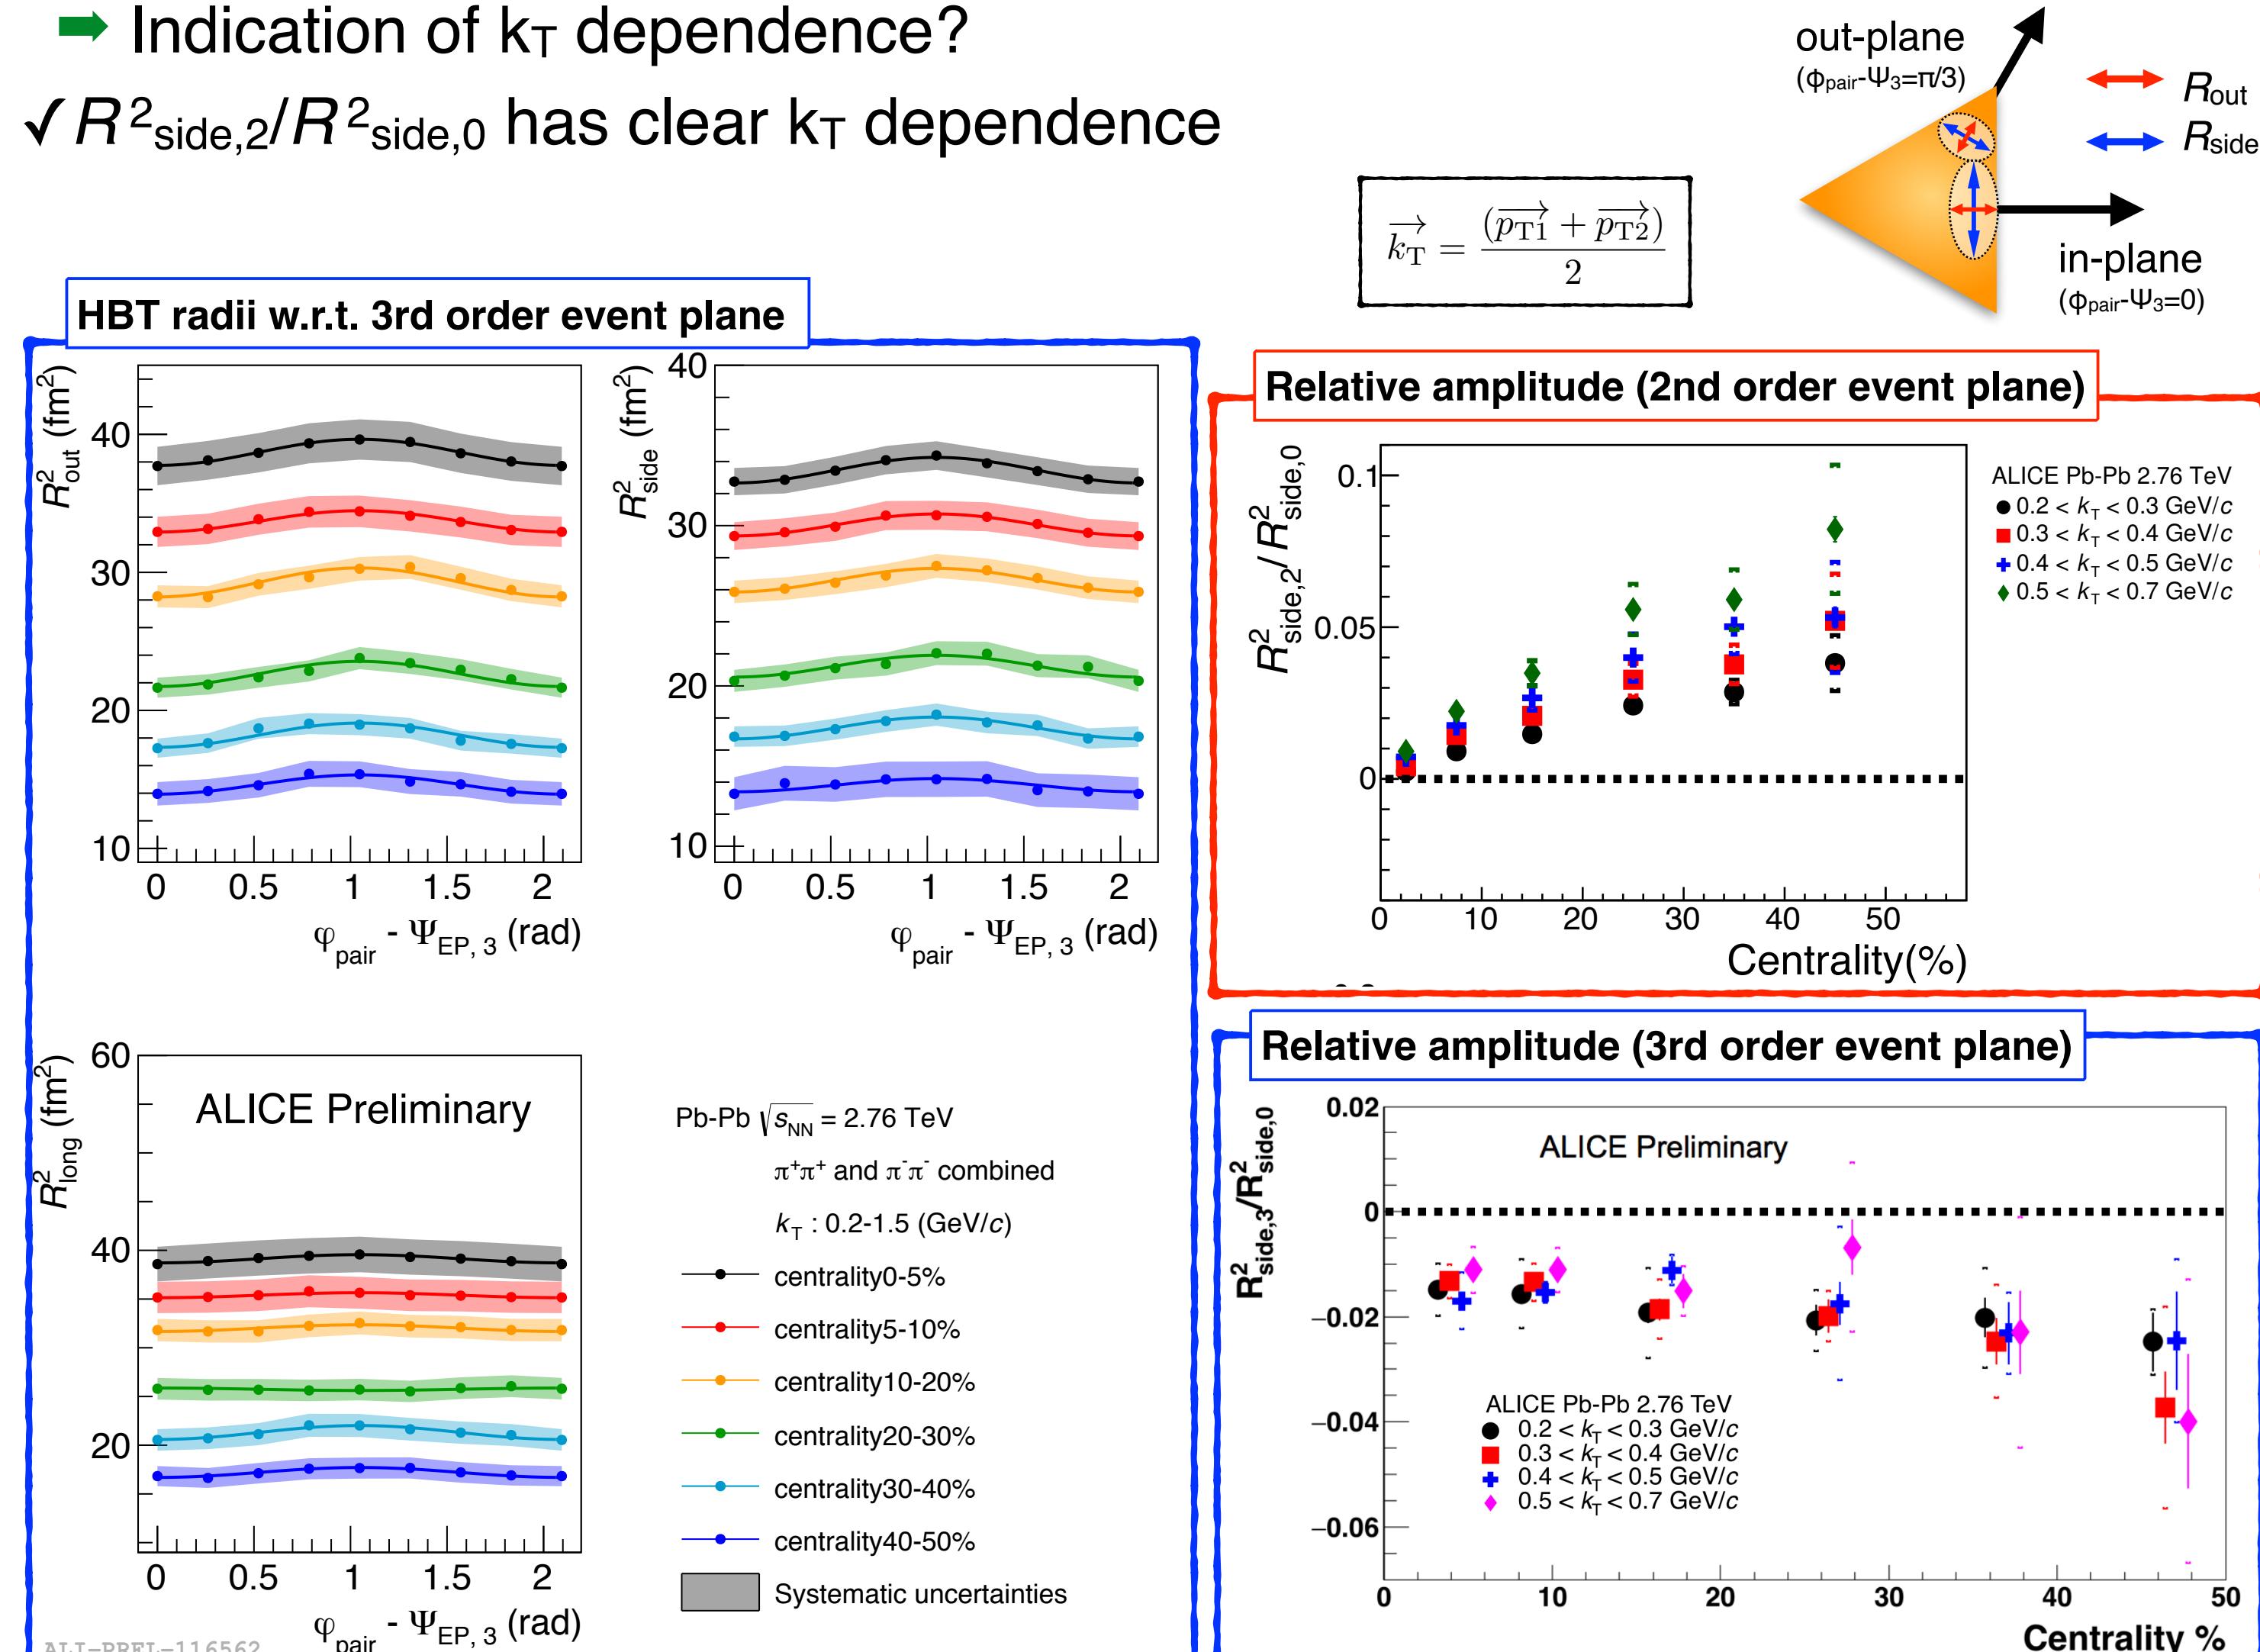

Event shape engineering(ESE) is a technique proposed to select event by event flow fluctuations[1].

Azimuthally differential HBT with large  $v_2$  and  $v_3$  event selection will give us the new insights into the **relation between anisotropic flow and the source shape at freeze out and the dynamics of system evolution**.

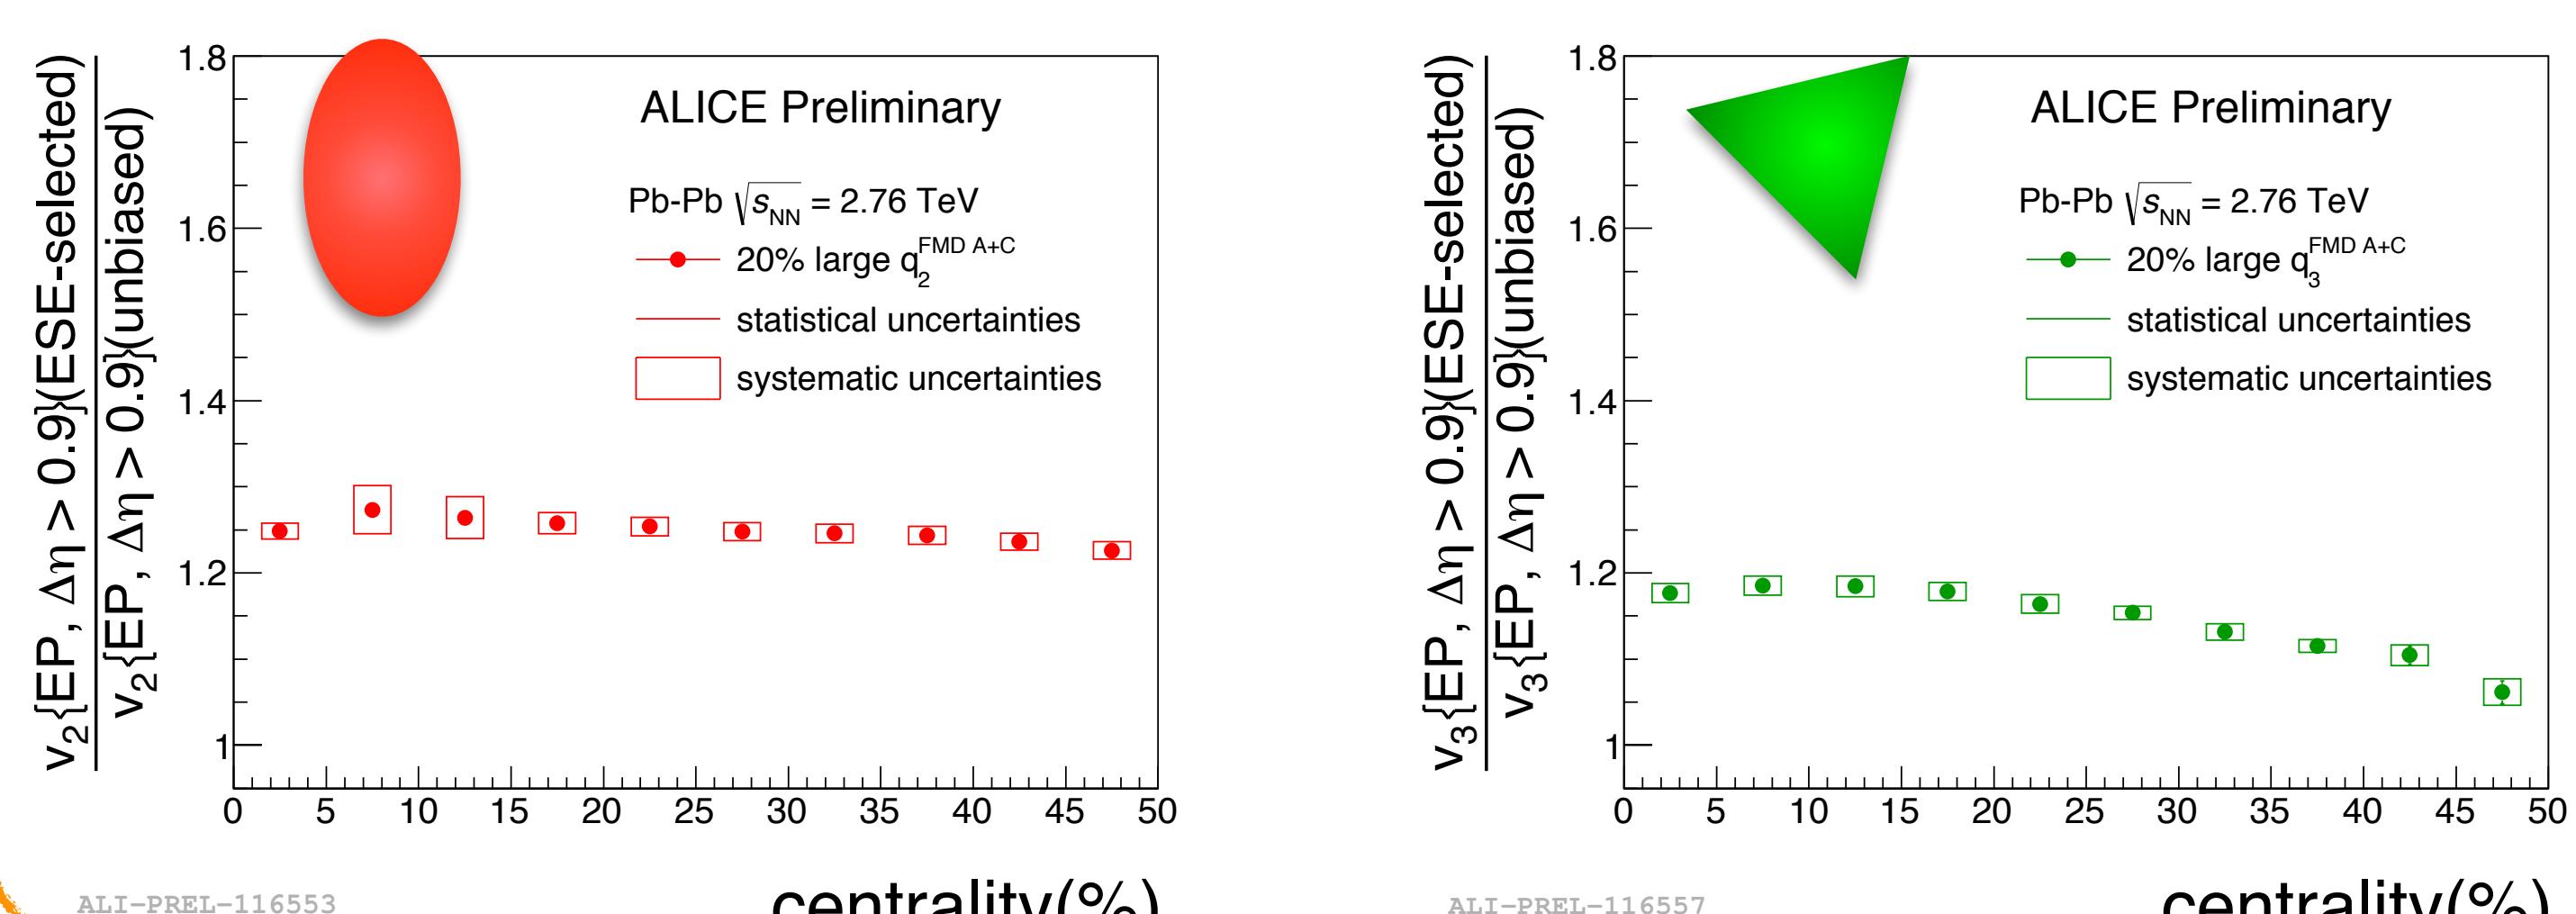

## HBT radii w.r.t $\Psi_3$

- ✓ 3<sup>rd</sup> order oscillation of HBT radii was observed in  $R_{\text{out}}$  and  $R_{\text{side}}$
- ✓ **Same sign oscillation of  $R_{\text{out}}$  and  $R_{\text{side}}$** , while opposite sign in 2<sup>nd</sup> order event plane dependence
- ✓  $R_{\text{side},3}/R_{\text{side},0}$  is **negative** without strong centrality dependence
- ✓  $R_{\text{side},2}/R_{\text{side},0}$  is positive with substantial centrality dependence
- ✓  $R_{\text{side},3}/R_{\text{side},0}$  in lowest  $k_T$  is smaller than that in highest  $k_T$ 
  - ➡ Indication of  $k_T$  dependence?
- ✓  $R_{\text{side},2}/R_{\text{side},0}$  has clear  $k_T$  dependence

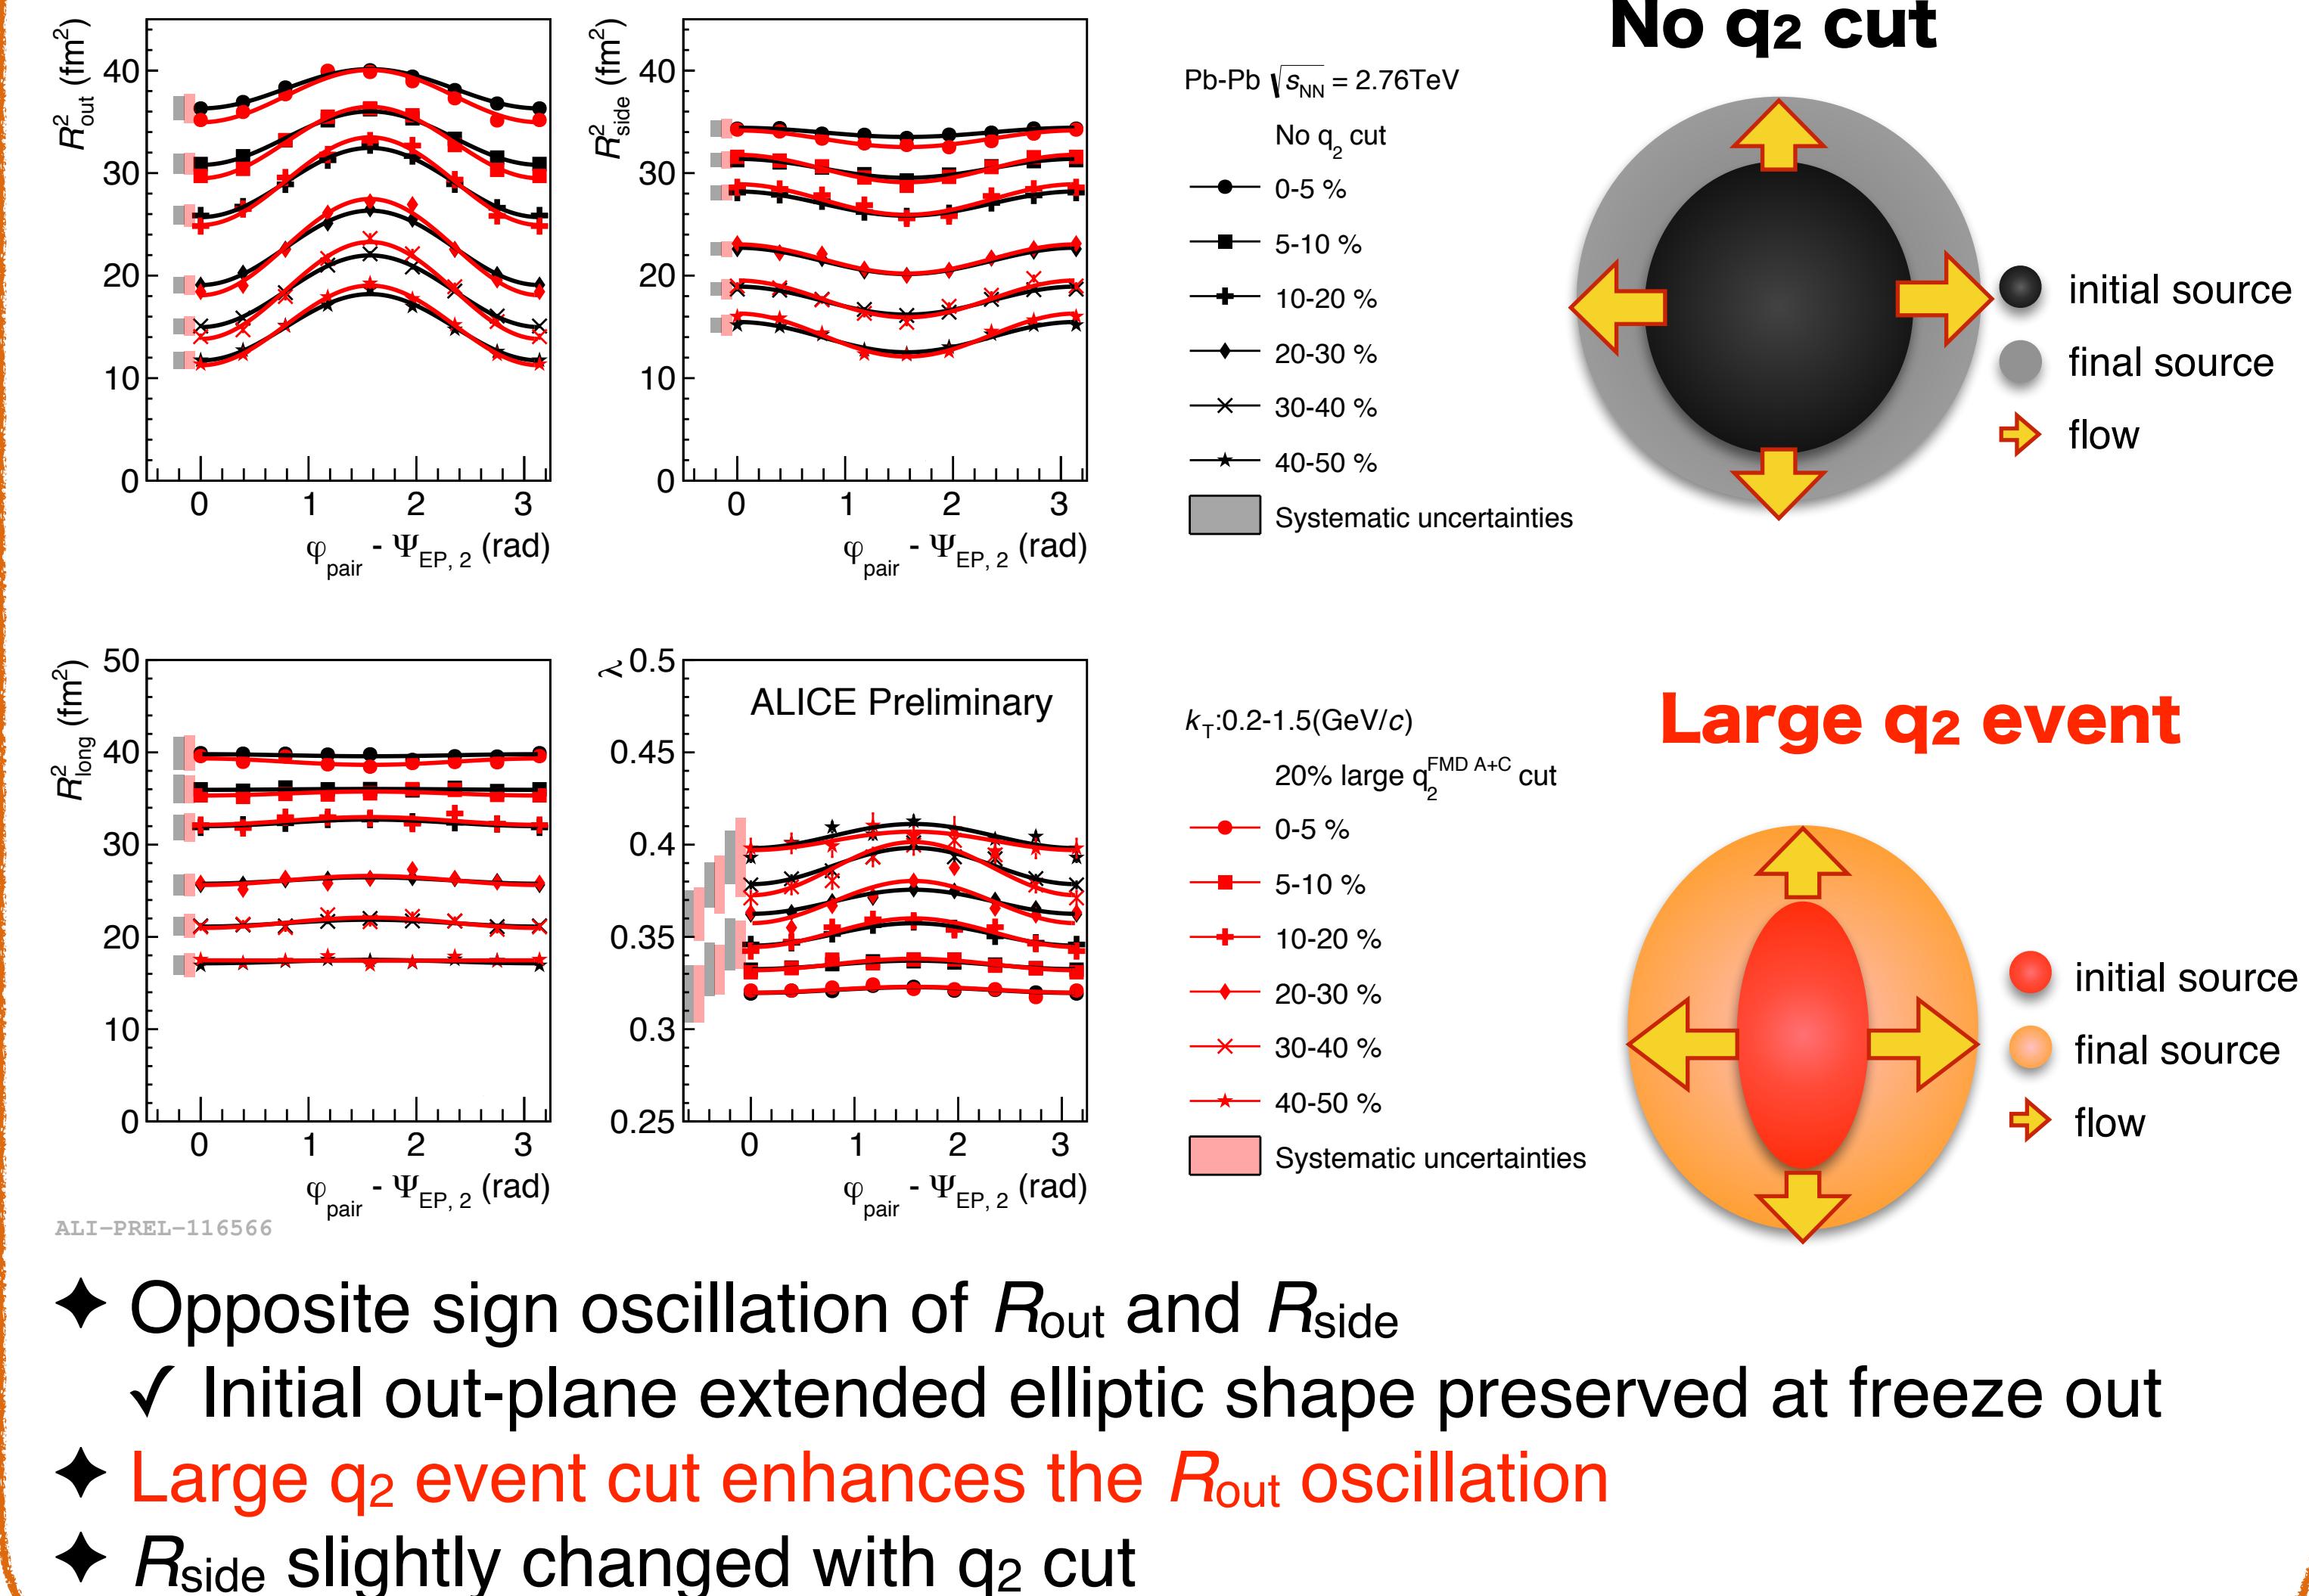

## Event shape engineering

- ✓  $v_2$  and  $v_3$  fluctuate event by event even in a same centrality
  - ✓ Q vector selection allows us to select event by event flow amplitude
- $$q_n = (q_{n,x}^2 + q_{n,y}^2)/\sqrt{M}$$
- ♦ Large  $v_2$  and  $v_3$  events can be selected with 20% largest  $q_2$  and  $q_3$  vector selection

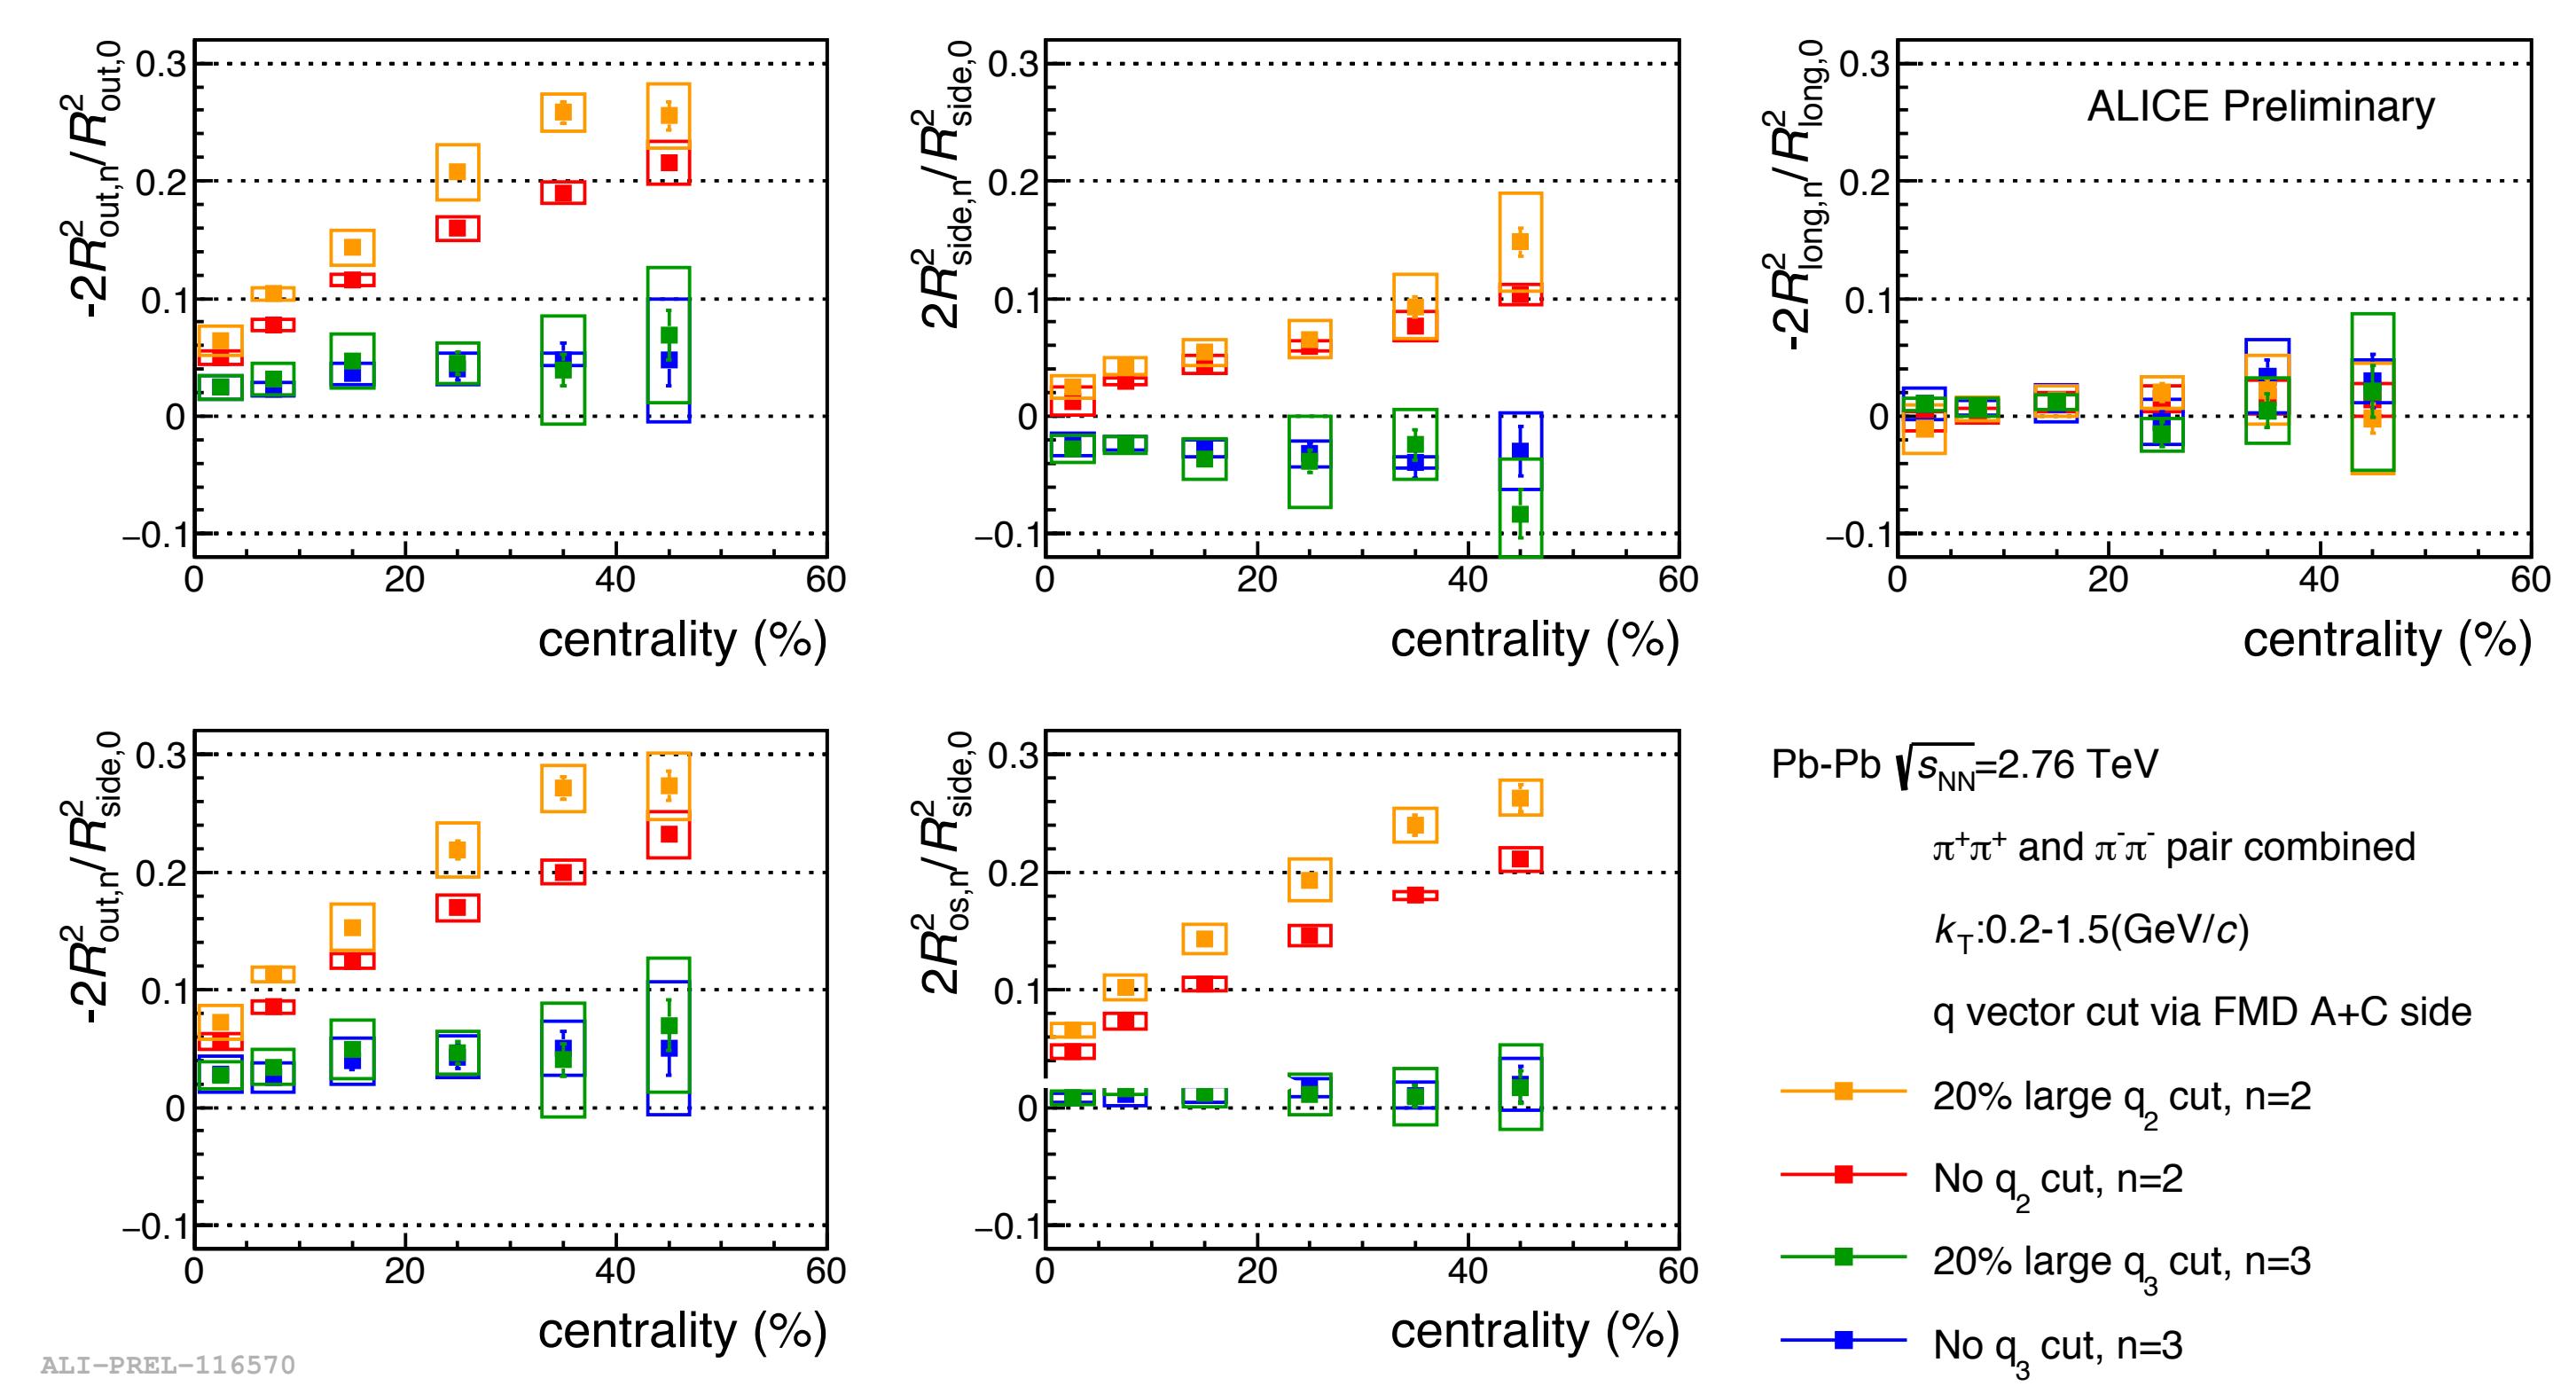

## Radii oscillation with ESE

- ♦ Opposite sign oscillation of  $R_{\text{out}}$  and  $R_{\text{side}}$
- ✓ Initial out-plane extended elliptic shape preserved at freeze out
- ♦ Large  $q_2$  event cut enhances the  $R_{\text{out}}$  oscillation
- ♦  $R_{\text{side}}$  slightly changed with  $q_2$  cut

## Relative amplitude with ESE

- ♦ 20% largest  $q_2$  cut
- ✓  $R_{\text{out},2}/R_{\text{out},0}$ ,  $R_{\text{out},2}/R_{\text{side},0}$ ,  $R_{\text{os},2}/R_{\text{out},0}$  increase by ~20% larger, while  $R_{\text{side},2}/R_{\text{side},0}$  grows by ~10%
- ♦ 20% largest  $q_3$  cut
- ✓ Although  $v_3$  is 20% enhanced with q vector cut, **relative amplitude does not change significantly**

## Conclusion

- ✓ Oscillation w.r.t. 3rd order event plane can be seen in  $R_{\text{out}}$  and  $R_{\text{side}}$
- ✓ ALICE has performed the first measurement of azimuthally sensitive femtoscopy with  $q_2$  and  $q_3$  selection
- ✓ Large  $q_2$  selection enhances the oscillation of HBT radii
- ✓ A significant effect of large  $q_3$  selection on 3<sup>rd</sup> order oscillation of HBT radii is not observed
